

Although currently our UI does not have a specific scanning pattern, I think it would be relevant to consider implementing one to improve the effectiveness and efficiency of the interface. In this sense, text scanning patterns can be a valuable tool to improve the user experience, especially if we are designing a web page with a lot of textual content.

For example, the F pattern or the Z pattern could be interesting options for organizing content and making it easier for the end user to scan. Therefore, considering text scanning patterns in our UI could be a way to improve usability and ultimately user satisfaction with our product.

In conclusion, understanding the patterns of text scanning on web pages is important to improve the user experience and optimize the readability and usability of the content. By taking these patterns into account when designing websites, you can improve the effectiveness and efficiency of the design and provide a more satisfying user experience.
